## **ENTANGLED FABRICS**

### **Background of the Invention**

Domestic and industrial wipers are often used to quickly absorb both polar liquids (e.g., water and alcohols) and nonpolar liquids (e.g., oil). The wipers must have a sufficient absorption capacity to hold the liquid within the wiper structure until it is desired to remove the liquid by pressure, e.g., wringing. In addition, the wipers must also possess good physical strength and abrasion resistance to withstand the tearing, stretching and abrading forces often applied during use. Moreover, the wipers should also be soft to the touch.

In the past, nonwoven fabrics, such as meltblown nonwoven webs, have been widely used as wipers. Meltblown nonwoven webs possess an interfiber capillary structure that is suitable for absorbing and retaining liquid. However, meltblown nonwoven webs sometimes lack the requisite physical properties for use as a heavy-duty wiper, e.g., tear strength and abrasion resistance. Consequently, meltblown nonwoven webs are typically laminated to a support layer, e.g., a spunbond nonwoven web, which may not be desirable for use on abrasive or rough surfaces.

Spunbond and staple fiber nonwoven webs, which contain thicker and stronger fibers than meltblown nonwoven webs and typically are point bonded with heat and pressure, can provide good physical properties, including tear strength and abrasion resistance. However, spunbond and staple fiber nonwoven webs sometimes lack fine interfiber capillary structures that enhance the adsorption characteristics of the wiper. Furthermore, spunbond and staple fiber nonwoven webs often contain bond points that may inhibit the flow or transfer of liquid within the nonwoven webs.

As such, a need remains for a fabric that is strong, soft, and also exhibits good absorption properties for use in a wide variety of wiper

applications.

### **Summary of the Invention**

5 In accordance with one aspect of the present invention, a method is disclosed for forming a fabric. The method includes forming a nonwoven web that defines a first surface and a second surface. The nonwoven web comprises splittable multicomponent fibers having individual segments exposed on an outer perimeter thereof. The splittable multicomponent fibers can generally possess a variety of different configurations that allow segments to be separated therefrom. For instance, in some  
10 embodiments, the multicomponent fibers have a configuration selected from the group consisting of circular, square, multilobal, ribbon, and combinations thereof.

15 In addition, the splittable multicomponent fibers can also be formed from a variety of materials and using any known process. For instance, in some embodiments, the segments within the splittable multicomponent fibers comprise polyethylene, polypropylene, polyester, nylon, and combinations thereof. Moreover, in one embodiment, the splittable multicomponent fibers of the nonwoven web are continuous spunbonded thermoplastic fibers.

20 Once the nonwoven web is formed, a first surface of the web is adhered to a first creping surface from which the web is then creped. In one embodiment, for example, a creping adhesive is applied to the first surface of the nonwoven web in a spaced-apart pattern such that the first surface of the nonwoven web is adhered to the creping surface according  
25 to such spaced-apart pattern. Moreover, in some embodiments, the second surface of the nonwoven web can also be adhered to a second creping surface from which the web is then creped. Although not required, creping two surfaces of the web can sometimes enhance certain characteristics of the resulting fabric.

In some embodiments, before being creped, the web can stretched in a certain direction. For example, in one embodiment, the nonwoven web is mechanically stretched in the machine direction. As a result, the web can become "necked", thereby increasing the stretch of the web in the cross-machine direction. The nonwoven web can generally be stretched to any extent desired. For example, in some embodiments, the nonwoven web is stretched by about 10% to about 100% of its initial length, and in some embodiments, by about 25% to about 75% of its initial length.

The creped and optionally stretched nonwoven web is then entangled (e.g., hydraulic, air, mechanical, etc.) such that at least a portion of the individual segments become separated from the multicomponent fibers. If desired, the creped nonwoven web can be entangled with a fibrous material that includes cellulosic fibers. Besides cellulosic fibers, the fibrous material may further contain other types of fibers, such as synthetic staple fibers. In some embodiments, when utilized, the synthetic staple fibers can comprise between about 10% to about 20% by weight of the fibrous material and have an average fiber diameter of between about 1/4 inches to about 3/8 inches.

In accordance with another aspect of the present invention, a composite fabric is disclosed that comprises a creped nonwoven web that is entangled (e.g., hydraulic, air, mechanical, etc.) with a fibrous material that contains cellulosic fibers. The creped nonwoven web is formed from splittable multicomponent thermoplastic fibers having individual segments exposed on an outer perimeter thereof. In one embodiment, the splittable multicomponent fibers are continuous spunbonded thermoplastic fibers. Moreover, in some embodiments, the nonwoven web is also stretched.

Other features and aspects of the present invention are discussed in greater detail below.

### **Brief Description of the Drawings**

A full and enabling disclosure of the present invention, including the best mode thereof, directed to one of ordinary skill in the art, is set forth more particularly in the remainder of the specification, which makes reference to the appended figures in which:

5 Figs. 1-5 are cross-sectional views of exemplary multicomponent fibers suitable for use with the present invention;

Fig. 6 is a cross-sectional view of a multicomponent fiber having poorly defined individual segments that are not exposed on the outer surface of the multicomponent fiber;

10 Fig. 7 is a schematic illustration of a process for creping a nonwoven substrate in accordance with one embodiment of the present invention; and

15 Fig. 8 is a schematic illustration of a process for forming a hydraulically entangled composite fabric in accordance with one embodiment of the present invention.

Repeat use of reference characters in the present specification and drawings is intended to represent same or analogous features or elements of the invention.

#### **Detailed Description of Representative Embodiments**

20 Reference now will be made in detail to various embodiments of the invention, one or more examples of which are set forth below. Each example is provided by way of explanation of the invention, not limitation of the invention. In fact, it will be apparent to those skilled in the art that various modifications and variations can be made in the present invention without departing from the scope or spirit of the invention. For instance,  
25 features illustrated or described as part of one embodiment, can be used on another embodiment to yield a still further embodiment. Thus, it is intended that the present invention covers such modifications and variations as come within the scope of the appended claims and their  
30 equivalents.

### Definitions

As used herein the term "nonwoven fabric or web" means a web having a structure of individual fibers or threads which are interlaid, but not in an identifiable manner as in a knitted fabric. Nonwoven fabrics or webs have been formed from many processes such as for example, meltblowing processes, spunbonding processes, bonded carded web processes, etc. The basis weight of nonwoven fabrics is usually expressed in ounces of material per square yard (osy) or grams per square meter (gsm) and the fiber diameters useful are usually expressed in microns. (Note that to convert from osy to gsm, multiply osy by 33.91).

As used herein the term "microfibers" means small diameter fibers having an average diameter not greater than about 75 microns, for example, having an average diameter of from about 0.5 microns to about 50 microns, or more particularly, microfibers may have an average diameter of from about 2 microns to about 40 microns.

As used herein, the term "meltblown fibers" refers to fibers formed by extruding a molten thermoplastic material through a plurality of fine, usually circular, die capillaries as molten fibers into converging high velocity gas (e.g. air) streams that attenuate the fibers of molten thermoplastic material to reduce their diameter, which may be to microfiber diameter. Thereafter, the meltblown fibers are carried by the high velocity gas stream and are deposited on a collecting surface to form a web of randomly disbursed meltblown fibers. Such a process is disclosed, for example, in U.S. Pat. No. 3,849,241 to Butin, et al., which is incorporated herein in its entirety by reference thereto for all purposes. Generally speaking, meltblown fibers may be microfibers that may be continuous or discontinuous, are generally smaller than 10 microns in diameter, and are generally tacky when deposited onto a collecting surface.

As used herein, the term "spunbonded fibers" refers to small diameter substantially continuous fibers that are formed by extruding a

molten thermoplastic material as filaments from a plurality of fine, usually circular, capillaries of a spinnerette with the diameter of the extruded fibers then being rapidly reduced as by, for example, eductive drawing and/or other well-known spunbonding mechanisms. The production of spunbonded nonwoven webs is described and illustrated, for example, in U.S. Patent Nos. 4,340,563 to Appel, et al., 3,692,618 to Dorschner, et al., 3,802,817 to Matsuki, et al., 3,338,992 to Kinney, 3,341,394 to Kinney, 3,502,763 to Hartman, 3,502,538 to Levy, 3,542,615 to Dobo, et al., and 5,382,400 to Pike, et al., which are incorporated herein in their entirety by reference thereto for all purposes. Spunbond fibers are generally not tacky when they are deposited onto a collecting surface. Spunbond fibers can sometimes have diameters less than about 40 microns, and are often between about 5 to about 20 microns.

As used herein, the term "pulp" refers to fibers from natural sources such as woody and non-woody plants. Woody plants include, for example, deciduous and coniferous trees. Non-woody plants include, for example, cotton, flax, esparto grass, milkweed, straw, jute hemp, and bagasse.

As used herein, the term "average fiber length" refers to a weighted average length of pulp fibers determined utilizing a Kajaani fiber analyzer model No. FS-100 available from Kajaani Oy Electronics, Kajaani, Finland. According to the test procedure, a pulp sample is treated with a macerating liquid to ensure that no fiber bundles or shives are present. Each pulp sample is disintegrated into hot water and diluted to an approximately 0.001% solution. Individual test samples are drawn in approximately 50 to 100 ml portions from the dilute solution when tested using the standard Kajaani fiber analysis test procedure. The weighted average fiber length may be expressed by the following equation:

$$\sum_{x_i}^k (x_i * n_i) / n$$

wherein,

$k$  = maximum fiber length  $x_i$  = fiber length

$n_i$  = number of fibers having length  $x_i$ ; and

$n$  = total number of fibers measured.

As used herein, the term "low-average fiber length pulp" refers to pulp that contains a significant amount of short fibers and non-fiber particles. Many secondary wood fiber pulps may be considered low average fiber length pulps; however, the quality of the secondary wood fiber pulp will depend on the quality of the recycled fibers and the type and amount of previous processing. Low-average fiber length pulps may have an average fiber length of less than about 1.2 mm as determined by an optical fiber analyzer such as, for example, a Kajaani fiber analyzer model No. FS-100 (Kajaani Oy Electronics, Kajaani, Finland). For example, low average fiber length pulps may have an average fiber length ranging from about 0.7 to 1.2 mm. Exemplary low average fiber length pulps include virgin hardwood pulp, and secondary fiber pulp from sources such as, for example, office waste, newsprint, and paperboard scrap.

As used herein, the term "high-average fiber length pulp" refers to pulp that contains a relatively small amount of short fibers and non-fiber particles. High-average fiber length pulp is typically formed from certain non-secondary (i.e., virgin) fibers. Secondary fiber pulp that has been screened may also have a high-average fiber length. High-average fiber length pulps typically have an average fiber length of greater than about 1.5 mm as determined by an optical fiber analyzer such as, for example, a Kajaani fiber analyzer model No. FS-100 (Kajaani Oy Electronics, Kajaani, Finland). For example, a high-average fiber length pulp may have an average fiber length from about 1.5 mm to about 6 mm. Exemplary high-average fiber length pulps that are wood fiber pulps include, for example, bleached and unbleached virgin softwood fiber pulps.

As used herein, the term "multicomponent fibers" or "conjugate fibers" refers to fibers that have been formed from at least two polymer

components. Such fibers are usually extruded from separate extruders but spun together to form one fiber. The polymers of the respective components are usually different from each other although multicomponent fibers may include separate components of similar or identical polymeric materials. The individual components are typically arranged in substantially constantly positioned distinct zones across the cross-section of the fiber and extend substantially along the entire length of the fiber. The configuration of such fibers may be, for example, a side-by-side arrangement, a pie arrangement, or any other arrangement. Bicomponent fibers and methods of making the same are taught in U.S. Patent Nos. 5,108,820 to Kaneko, et al., 4,795,668 to Kruege, et al., 5,382,400 to Pike, et al., 5,336,552 to Strack, et al., and 6,200,669 to Marmon, et al., which are incorporated herein in their entirety by reference thereto for all purposes. The fibers and individual components containing the same may also have various irregular shapes such as those described in U.S. Patent. Nos. 5,277,976 to Hogle, et al., 5,162,074 to Hills, 5,466,410 to Hills, 5,069,970 to Largman, et al., and 5,057,368 to Largman, et al., which are incorporated herein in their entirety by reference thereto for all purposes.

As used herein, the term "fiber" refers to an elongated extrudate formed by passing a polymer through a forming orifice such as a die. Unless noted otherwise, the term "fibers" includes discontinuous strands having a definite length and continuous strands of material, such as filaments.

#### Detailed Description

In general, the present invention is directed to a fabric that is formed from an entangled nonwoven web that contains splittable multicomponent fibers. The nonwoven web is creped and optionally stretched to improve various properties of the resulting fabric. In some embodiments, for example, the nonwoven web is hydraulically entangled

with a fibrous material that includes cellulosic fibers and optionally synthetic staple fibers. By using splittable multicomponent fibers to form the nonwoven web, various segments of the multicomponent fibers can separate therefrom during entanglement, thereby improving the bulk, softness, and capillary tension of the resulting fabric.

The nonwoven web used in the fabric of the present invention may be formed by a variety of different processes and from a variety of different materials. For example, in some embodiments, the nonwoven web includes splittable, multicomponent fibers. In fabricating multicomponent fibers that are also splittable, the individual segments that collectively form the unitary multicomponent fiber are contiguous along the longitudinal direction of the multicomponent fiber in a manner such that one or more segments form part of the outer surface of the unitary multicomponent fiber. In other words, one or more segments are exposed along the outer perimeter of the multicomponent fiber. For example, referring to Fig. 1, a unitary multicomponent fiber 110 is shown, having a side-by-side configuration, with a first segment 112A forming part of the outer surface of the multicomponent fiber 110 and a second segment 112B forming the remainder of the outer surface of the multicomponent fiber 110.

A particularly useful configuration, as shown in Fig. 2, is a plurality of radially extending wedge-like shapes, which in reference to the cross-section of the segments, are thicker at the outer surface of the multicomponent fiber 110 than at the inner portion of the multicomponent fiber 110. In one aspect, the multicomponent fiber 110 may have an alternating series of individual wedge-shaped segments 112A and 112B of different polymeric materials.

In addition to circular fiber configurations, the multicomponent fibers may have other shapes, such as square, multilobal, ribbon and/or other shapes. Additionally, as shown in Fig. 3, multicomponent fibers may be employed that have alternating segments 114A and 114B about a hollow

center 116. In a further aspect, as shown in Fig. 4, a multicomponent fiber 110 suitable for use with the present invention may comprise individual segments 118A and 118B wherein a first segment 118A comprises a single fiber with radially extending arms 119 that separate a plurality of additional segments 118B. Although separation should occur between the components 118A and 118B, it may often not occur between the lobes or arms 119 due to the central core 120 connecting the individual arms 119. Thus, in order to achieve more uniform fibers, it may often be desirable that the individual segments do not have a cohesive central core. For example, as shown in Fig. 5, alternating segments 112A and 112B forming the multicomponent fiber 110 may extend across the entire cross-section of the fiber. As discussed below, it will also be appreciated that the individual segments may contain identical or similar materials as well as two or more different materials.

The individual segments, although of varied shape, typically have distinct boundaries or zones across the cross-section of the fiber. Forming a hollow fiber type multicomponent fiber may be desired with some materials in order to inhibit segments of like material from bonding or fusing at contact points in the inner portion of the multicomponent fiber. Further, as mentioned above, it may also be desired that the shapes are well defined or "distinct" in that they do not overlap adjacent segments along the outer surface of the multicomponent fiber. For example, as shown in Fig. 6, alternating segments 122A and 122B are shown wherein portions of segments 122B "wrap around" the outer portion of the adjacent segments 122A. This overlap will often impede and/or prevent separation of the individual segments, particularly where segment 122A is fully engulfed by adjacent segments 122B. Thus, "wrap around" is therefore avoided and the formation of well defined or distinct shapes highly desirable.

In some instances, matching the viscosities of the respective thermoplastic materials may help inhibit the "wrap-around" discussed above. This may be accomplished in a variety of different ways. For example, the temperatures of the respective materials may be run at opposed ends of their melt ranges or processing window; e.g., when forming a pie shaped multicomponent fiber from nylon and polyethylene, the polyethylene may be heated to a temperature near the lower limit of its melt range (about 390°C) and the nylon may be heated to a temperature near the upper limit of its melt range (about 500°C). In this regard, one of the components could be brought into the spin-pack at a temperature below that of the spin pack such that it is processed at a temperature near the lower end of its processing window, whereas the other material may be introduced at a temperature to ensure processing at the upper end of its processing window. In addition, it is known in the art that certain additives may be employed to either reduce or increase the viscosity of the polymeric materials as desired.

The multicomponent fibers used to form the nonwoven web can also be formed such that the size of the individual segments and their respective polymeric materials are disproportionate to one another. The individual segments may be varied as much as 95:5 by volume, although ratios of 80:20 or 75:25 may be more easily fabricated. For example, in one embodiment, as shown in Fig. 3, individual segments 114A and 114B have a disproportionate size with respect to each other. For instance, if one of the polymers forming the segments is significantly more expensive than the polymers forming the remaining segments, the amount of the expensive polymeric material may be reduced by decreasing the size of its respective segments.

A wide variety of polymeric materials are known to be suitable for use in fabricating the splittable, multicomponent fibers used in the present invention. Examples include, but are not limited to, polyolefins, polyesters,

polyamides, as well as other melt-spinnable and/or fiber forming polymers. The polyamides that may be used in the practice of this invention may be any polyamide known to those skilled in the art including copolymers and mixtures thereof. Examples of polyamides and their methods of synthesis may be found in "Polymer Resins" by Don E. Floyd (Library of Congress Catalog number 66-20811, Reinhold Publishing, NY, 1966). Particularly commercially useful polyamides are nylon-6, nylon 66, nylon-11 and nylon-12. These polyamides are available from a number of sources, such as Emser Industries of Sumter, S.C. (Grilon® & Grilamid® nylons) and Atochem, Inc. Polymers Division, of Glen Rock, N.J. (Rilsan® nylons), among others. Many polyolefins are available for fiber production, for example, polyethylenes such as Dow Chemical's ASPUN® 6811A LLDPE (linear low density polyethylene), 2553 LLDPE and 25355 and 12350 high density polyethylene are such suitable polymers. Fiber forming polypropylenes include Exxon Chemical Company's Escorene® PD 3445 polypropylene and Himont Chemical Co.'s PF-304. Numerous other suitable fiber forming polyolefins, in addition to those listed above, are also commercially available.

Although numerous materials are suitable for use in melt-spinning or other multicomponent fiber fabrication processes, because the multicomponent fibers may contain two or more different materials, one skilled in the art will appreciate that specific materials may not be suitable for use with all other materials. Thus, the composition of the materials forming the individual segments of the multicomponent fibers are typically selected, in one aspect, with a view towards the compatibility of the materials with those of adjacent segments. In this regard, the materials forming the individual segments are generally not miscible with the materials forming adjacent segments and desirably have a poor mutual affinity for the same. Selecting polymeric materials that tend to significantly adhere to one another under the processing conditions may

increase the impact energy required to separate the segments and may also decrease the degree of separation achieved between the individual segments of the unitary multicomponent fibers. It is, therefore, often desirable that adjacent segments are formed from dissimilar materials.

5 For example, adjacent segments may generally contain a polyolefin and a non-polyolefin, e.g., including alternating components of the following materials: nylon-6 and polyethylene; nylon-6 and polypropylene; polyester and HDPE (high density polyethylene). Other combinations also believed suitable for use in the present invention include, but are not limited to, nylon-6 and polyester, and, polypropylene and HDPE.

10 Although not required, the splittable, multicomponent fibers used to form the nonwoven web may also be bonded to improve the durability, strength, hand, aesthetics and/or other properties of the web. For instance, the nonwoven web can be thermally, ultrasonically, adhesively and/or mechanically bonded. As an example, the nonwoven web can be point bonded such that it possesses numerous small, discrete bond points. An exemplary point bonding process is thermal point bonding, which generally involves passing one or more layers between heated rolls, such as an engraved patterned roll and a second bonding roll. The engraved roll is patterned in some way so that the web is not bonded over its entire surface, and the second roll can be smooth or patterned. As a result, various patterns for engraved rolls have been developed for functional as well as aesthetic reasons. Exemplary bond patterns include, but are not limited to, those described in U.S. Patent Nos. 3,855,046 to Hansen, et al., 15 5,620,779 to Levy, et al., 5,962,112 to Haynes, et al., 6,093,665 to Sayovitz, et al., U.S. Design Patent No. 428,267 to Romano, et al. and U.S. Design Patent No. 390,708 to Brown, which are incorporated herein in their entirety by reference thereto for all purposes. For instance, in some embodiments, the nonwoven web may be optionally bonded to have a total bond area of less than about 30% (as determined by conventional 20 25 30

optical microscopic methods) and/or a uniform bond density greater than about 100 bonds per square inch. For example, the nonwoven web may have a total bond area from about 2% to about 30% and/or a bond density from about 250 to about 500 pin bonds per square inch. Such a combination of total bond area and/or bond density may, in some embodiments, be achieved by bonding the nonwoven web with a pin bond pattern having more than about 100 pin bonds per square inch that provides a total bond surface area less than about 30% when fully contacting a smooth anvil roll. In some embodiments, the bond pattern may have a pin bond density from about 250 to about 350 pin bonds per square inch and/or a total bond surface area from about 10% to about 25% when contacting a smooth anvil roll.

Further, the nonwoven web can be bonded by continuous seams or patterns. As additional examples, the nonwoven web can be bonded along the periphery of the sheet or simply across the width or cross-direction (CD) of the web adjacent the edges. Other bond techniques, such as a combination of thermal bonding and latex impregnation, may also be used. Alternatively and/or additionally, a resin, latex or adhesive may be applied to the nonwoven web by, for example, spraying or printing, and dried to provide the desired bonding. Still other suitable bonding techniques may be described in U.S. Patent Nos. 5,284,703 to Everhart, et al., 6,103,061 to Anderson, et al., and 6,197,404 to Varona, which are incorporated herein in its entirety by reference thereto for all purposes.

Regardless of whether the nonwoven web is bonded, it is typically creped. Creping can impart microfolds into the web to provide a variety of different characteristics thereto. For instance, creping can open the pore structure of the nonwoven web, thereby increasing its permeability. Moreover, creping can also enhance the stretchability of the web in the machine and/or cross-machine directions, as well as increase its softness and bulk.

Various techniques for creping nonwoven webs are described in U.S. Patent No. 6,197,404 to Varona. For instance, Fig. 7 illustrates one embodiment of a creping process that can be used to crepe on or both sides of a nonwoven web 20. For instance, the nonwoven web 20 may be passed through a first creping station 60, a second creping station 70, or both. If it is desired to crepe the nonwoven web 20 on only one side, it may be passed through either the first creping station 60 or the second creping station 70, with one creping station or the other being bypassed. If it is desired to crepe the nonwoven web 20 on both sides, it may be passed through both creping stations 60 and 70.

A first side 83 of the web 20 may be creped using the first creping station 60. The creping station 60 includes first a printing station having a lower patterned or smooth printing roller 62, an upper smooth anvil roller 64, and a printing bath 65, and also includes a dryer roller 66 and associated creping blade 68.

The rollers 62 and 64 nip the web 20 and guide it forward. As the rollers 62 and 64 turn, the patterned or smooth printing roller 62 dips into bath 65 containing an adhesive material, and applies the adhesive material to the first side 83 of the web 20 in a partial coverage at a plurality of spaced apart locations, or in a total coverage. The adhesive-coated web 20 is then passed around drying drum 66 whereupon the adhesive-coated surface 83 becomes adhered to the roller 66. The first side 83 of the web 20 is then creped (i.e., lifted off the drum and bent) using doctor blade 68.

A second side 85 of the web 20 may be creped using the second creping station 70, regardless of whether or not the first creping station 60 has been bypassed. The second creping station 70 includes a second printing station including a lower patterned or smooth printing roller 72, an upper smooth anvil roller 74, and a printing bath 75, and also includes a dryer drum 76 and associated creping blade 78. The rollers 72 and 74 nip

the web 20 and guide it forward. As the rollers 72 and 74 turn, the printing roller 72 dips into bath 75 containing adhesive material, and applies the adhesive to the second side 85 of the web 20 in a partial or total coverage. The adhesive-coated web 20 is then passed around drying roller 76 whereupon the adhesive-coated surface 85 becomes adhered to the roller 76. The second side 85 of the web 20 is then creped using doctor blade 78. After creping, the nonwoven web 20 may be passed through a chilling station 80 and wound onto a storage roll 82 before being entangled.

The adhesive materials applied to the web 20 at the first and/or second printing stations may enhance the adherence of the substrate to the creping drum, as well as reinforce the fibers of the web 20. For instance, in some embodiments, the adhesive materials may bond the web to such an extent that the optional bonding techniques described above are not utilized.

A wide variety of adhesive materials may generally be utilized to reinforce the fibers of the web 20 at the locations of adhesive application, and to temporarily adhere the web 20 to the surface of the drums 66 and/or 76. Elastomeric adhesives (i.e., materials capable of at least 75% elongation without rupture) are especially suitable. Suitable materials include without limitation aqueous-based styrene butadiene adhesives, neoprene, polyvinyl chloride, vinyl copolymers, polyamides, ethylene vinyl terpolymers and combinations thereof. For instance, one adhesive material that can be utilized is an acrylic polymer emulsion sold by the B. F. Goodrich Company under the trade name HYCAR®. The adhesive may be applied using the printing technique described above or may, alternatively, be applied by meltblowing, melt spraying, dripping, splattering, or any other technique capable of forming a partial or total adhesive coverage on the nonwoven web 20.

The percent adhesive coverage of the web 20 can be selected to obtain varying levels of creping. For instance, the adhesive can cover

between about 5% to 100% of the web surface, in some embodiments between about 10% to about 70% of the web surface, and in some embodiments, between about 25% to about 50% of the web surface. The adhesive can also penetrate the nonwoven web 20 in the locations where the adhesive is applied. In particular, the adhesive typically penetrates through about 10% to about 50% of the nonwoven web thickness, although there may be greater or less adhesive penetration at some locations.

Optionally, the nonwoven web 20 can also be stretched in the machine and/or cross-machine directions before creping. Stretching of the web 20 can be used to optimize and enhance physical properties in the fabric including, but not limited to, softness, bulk, stretchability and recovery, permeability, basis weight, density, and liquid holding capacity. For example, in one embodiment, the web 20 can be mechanically stretched in the machine direction to cause the web 20 to contract or neck in the cross-machine direction. The resulting necked web 20 thus becomes more stretchable in the cross-machine direction. Mechanical stretching of the web 20 can be accomplished using any of a variety of processes that are well known in the art. For instance, the web 20 may be pre-stretched between about 0 to about 100% of its initial length in the machine direction to obtain a necked web that can be stretched (e.g., by about 0 to about 100%) in the cross-machine direction. Typically, the web 20 is stretched by about 10% to about 100% of its initial length, and more commonly by about 25% to about 75% of its initial length in the machine direction.

Once stretched, the web 20 can then be relatively dimensionally stabilized, first by the adhesive applied to the web 20, and second by the heat that is imparted during creping. This stabilization can set the cross-directional stretch properties of the web 20. The machine direction stretch is further stabilized by the out-of-plane deformation of the bonded areas of

the nonwoven web 20 that occurs during creping. Other stretching techniques can also be utilized in the present invention to apply stretching tension in the machine and/or cross-machine directions. For instance, an example of suitable stretching processes is a tenter frame process that utilizes a gripping device, e.g., clips, to hold the edges of the nonwoven web and apply the stretching force. Still other examples of stretching techniques that are believed to be suitable for use in the present invention are described in U.S. Patent No. 5,573,719 to Fitting, which is incorporated herein in its entirety by reference thereto for all purposes.

In accordance with the present invention, the nonwoven web is then entangled using any of a variety of entanglement techniques known in the art (e.g., hydraulic, air, mechanical, etc.). The nonwoven web may be entangled either alone, or in conjunction with other materials. For example, in some embodiments, the nonwoven web is integrally entangled with a cellulosic fiber component using hydraulic entanglement. The cellulosic fiber component can generally comprise any desired amount of the resulting fabric. For example, in some embodiments, the cellulosic fiber component can comprise greater than about 50% by weight of the fabric, and in some embodiments, between about 60% to about 90% by weight of the fabric.

When utilized, the cellulosic fiber component can contain cellulosic fibers (e.g., pulp, thermomechanical pulp, synthetic cellulosic fibers, modified cellulosic fibers, and the like), as well as other types of fibers (e.g., synthetic staple fibers). Some examples of suitable cellulosic fiber sources include virgin wood fibers, such as thermomechanical, bleached and unbleached softwood and hardwood pulps. Secondary or recycled fibers, such as obtained from office waste, newsprint, brown paper stock, paperboard scrap, etc., may also be used. Further, vegetable fibers, such as abaca, flax, milkweed, cotton, modified cotton, cotton linters, can also be used. In addition, synthetic cellulosic fibers such as, for example,

rayon and viscose rayon may be used. Modified cellulosic fibers may also be used. For example, the fibrous material may be composed of derivatives of cellulose formed by substitution of appropriate radicals (e.g., carboxyl, alkyl, acetate, nitrate, etc.) for hydroxyl groups along the carbon chain.

When utilized, pulp fibers may have any high-average fiber length pulp, low-average fiber length pulp, or mixtures of the same. High-average fiber length pulp fibers typically have an average fiber length from about 1.5 mm to about 6 mm. Some examples of such fibers may include, but are not limited to, northern softwood, southern softwood, redwood, red cedar, hemlock, pine (e.g., southern pines), spruce (e.g., black spruce), combinations thereof, and the like. Exemplary high-average fiber length wood pulps include those available from the Kimberly-Clark Corporation under the trade designation "Longlac 19".

The low-average fiber length pulp may be, for example, certain virgin hardwood pulps and secondary (i.e. recycled) fiber pulp from sources such as, for example, newsprint, reclaimed paperboard, and office waste. Hardwood fibers, such as eucalyptus, maple, birch, aspen, and the like, can also be used. Low-average fiber length pulp fibers typically have an average fiber length of less than about 1.2 mm, for example, from 0.7 mm to 1.2 mm. Mixtures of high-average fiber length and low-average fiber length pulps may contain a significant proportion of low-average fiber length pulps. For example, mixtures may contain more than about 50 percent by weight low-average fiber length pulp and less than about 50 percent by weight high-average fiber length pulp. One exemplary mixture contains 75% by weight low-average fiber length pulp and about 25% by weight high-average fiber length pulp.

As stated above, non-cellulosic fibers may also be utilized in the cellulosic fiber component. Some examples of suitable non-cellulosic fibers that can be used include, but are not limited to, polyolefin fibers,

polyester fibers, nylon fibers, polyvinyl acetate fibers, and mixtures thereof. In some embodiments, the non-cellulosic fibers can be staple fibers having, for example, an average fiber length of between about 0.25 inches to about 0.375 inches. When non-cellulosic fibers are utilized, the  
5 cellulose fiber component generally contains between about 80% to about 90% by weight cellulosic fibers, such as softwood pulp fibers, and between about 10% to about 20% by weight non-cellulosic fibers, such as polyester or polyolefin staple fibers.

Small amounts of wet-strength resins and/or resin binders may be added to the cellulosic fiber component to improve strength and abrasion resistance. Cross-linking agents and/or hydrating agents may also be added to the pulp mixture. Debonding agents may be added to the pulp mixture to reduce the degree of hydrogen bonding if a very open or loose nonwoven pulp fiber web is desired. The addition of certain debonding  
10 agents in the amount of, for example, about 1% to about 4% percent by weight of the fabric also appears to reduce the measured static and dynamic coefficients of friction and improve the abrasion resistance of the continuous filament rich side of the composite fabric. The debonding agent is believed to act as a lubricant or friction reducer.

Referring to Fig. 8, one embodiment of the present invention for hydraulically entangling a cellulosic fiber component with a nonwoven web that contains splittable, multicomponent fibers is illustrated. As shown, a fibrous slurry containing cellulosic fibers is conveyed to a conventional papermaking headbox 12 where it is deposited via a sluice 14 onto a  
15 conventional forming fabric or surface 16. The suspension of fibrous material may have any consistency that is typically used in conventional papermaking processes. For example, the suspension may contain from about 0.01 to about 1.5 percent by weight fibrous material suspended in water. Water is then removed from the suspension of fibrous material to  
20 form a uniform layer of the fibrous material 18.

The nonwoven web 20 is also unwound from a supply roll 22 and travels in the direction indicated by the arrow associated therewith as the supply roll 22 rotates in the direction of the arrows associated therewith. The nonwoven web 20 passes through a nip 24 of a S-roll arrangement 26 formed by the stack rollers 28 and 30. The nonwoven web 20 is then placed upon a foraminous entangling surface 32 of a conventional hydraulic entangling machine where the cellulosic fibrous layer 18 is then laid on the web 20. Although not required, it is typically desired that the cellulosic fibrous layer 18 be between the nonwoven web 20 and the hydraulic entangling manifolds 34. The cellulosic fibrous layer 18 and nonwoven web 20 pass under one or more hydraulic entangling manifolds 34 and are treated with jets of fluid to entangle the cellulosic fibrous material with the fibers of the nonwoven web 20. The jets of fluid also drive cellulosic fibers into and through the nonwoven web 20 to form the composite fabric 36.

Alternatively, hydraulic entangling may take place while the cellulosic fibrous layer 18 and nonwoven web 20 are on the same foraminous screen (e.g., mesh fabric) that the wet-laying took place. The present invention also contemplates superposing a dried cellulosic fibrous sheet on a nonwoven web, rehydrating the dried sheet to a specified consistency and then subjecting the rehydrated sheet to hydraulic entangling. The hydraulic entangling may take place while the cellulosic fibrous layer 18 is highly saturated with water. For example, the cellulosic fibrous layer 18 may contain up to about 90% by weight water just before hydraulic entangling. Alternatively, the cellulosic fibrous layer 18 may be an air-laid or dry-laid layer.

Hydraulic entangling may be accomplished utilizing conventional hydraulic entangling equipment such as described in, for example, in U.S. Pat. No. 3,485,706 to Evans, which is incorporated herein in its entirety by reference thereto for all purposes. Hydraulic entangling may be carried

out with any appropriate working fluid such as, for example, water. The working fluid flows through a manifold that evenly distributes the fluid to a series of individual holes or orifices. These holes or orifices may be from about 0.003 to about 0.015 inch in diameter and may be arranged in one or more rows with any number of orifices, e.g., 30-100 per inch, in each row. For example, a manifold produced by Honeycomb Systems Incorporated of Biddeford, Maine, containing a strip having 0.007-inch diameter orifices, 30 holes per inch, and 1 row of holes may be utilized. However, it should also be understood that many other manifold configurations and combinations may be used. For example, a single manifold may be used or several manifolds may be arranged in succession.

Fluid can impact the cellulosic fibrous layer 18 and the nonwoven web 20, which are supported by a foraminous surface, such as a single plane mesh having a mesh size of from about 40 x 40 to about 100 x 100. The foraminous surface may also be a multi-ply mesh having a mesh size from about 50 x 50 to about 200 x 200. As is typical in many water jet treatment processes, vacuum slots 38 may be located directly beneath the hydro-needling manifolds or beneath the foraminous entangling surface 32 downstream of the entangling manifold so that excess water is withdrawn from the hydraulically entangled composite material 36.

Although not held to any particular theory of operation, it is believed that the columnar jets of working fluid that directly impact cellulosic fibers 18 laying on the nonwoven web 20 work to drive those fibers into and partially through the matrix or network of fibers in the web 20. When the fluid jets and cellulosic fibers 18 interact with a nonwoven web 20, the cellulosic fibers 18 are also entangled with fibers of the nonwoven web 20 and with each other.

The impact of the pressurized streams of water also causes the individual segment(s) exposed on the outer perimeter of the splittable,

multicomponent fibers of the nonwoven web to separate from the multicomponent fiber. For example, splitting a multicomponent fiber having a relatively small diameter (e.g., spunbonded fibers having a diameter less than about 15 microns), and which has a plurality of individual segments exposed on its outer perimeter, can result in a web having numerous fine fibers, i.e., microfibers. These fine fibers or microfibers can enhance various properties of the resulting web. For instance, splitting the multicomponent fibers into various segments can increase the softness, bulk, and cross-machine direction strength of the resulting web.

To achieve the desired splitting of the multicomponent fibers, it is typically desired that hydroentangling be performed using water pressures from about 100 to 3000 psig, in some embodiments from about 120 to 500 psig, and in some embodiments, between about 150 psig to about 180 psig. When processed at the upper ranges of the described pressures, the composite fabric 36 may be processed at speeds of up to about 1000 feet per minute (fpm).

As indicated above the pressure of the jets in the entangling process is typically at least about 100 psig because lower pressures often do not generate the desired degree of separation. However, it should be understood that adequate separation may be achieved at substantially lower water pressures, particularly when utilizing higher quality cross-sectional shaped segments and/or by utilizing polymeric materials in adjacent segments that do not readily adhere to one another. In addition, greater separation may be achieved, in part, by subjecting the multicomponent fibers to the entangling process two or more times. Thus, it may be desirable that the web be subjected to at least one run under the entangling apparatus, wherein the water jets are directed to the first side and an additional run wherein the water jets are directed to the opposite side of the web.

After the fluid jet treatment, the resulting composite fabric 36 may then be transferred to a non-compressive drying operation. A differential speed pickup roll 40 may be used to transfer the material from the hydraulic needling belt to a non-compressive drying operation.

5 Alternatively, conventional vacuum-type pickups and transfer fabrics may be used. If desired, the composite fabric 36 may be wet-creped before being transferred to the drying operation. Non-compressive drying of the fabric 36 may be accomplished utilizing a conventional rotary drum through-air drying apparatus 42. The through-dryer 42 may be an outer rotatable cylinder 44 with perforations 46 in combination with an outer hood 48 for receiving hot air blown through the perforations 46. A through-dryer belt 50 carries the composite fabric 36 over the upper portion of the through-dryer outer cylinder 40. The heated air forced through the perforations 46 in the outer cylinder 44 of the through-dryer 42 removes water from the composite fabric 36. The temperature of the air forced through the composite fabric 36 by the through-dryer 42 may range from about 200°F to about 500°F. Other useful through-drying methods and apparatus may be found in, for example, U.S. Pat. Nos. 2,666,369 to Niks and 3,821,068 to Shaw, which are incorporated herein in their entirety by reference thereto for all purposes.

20 It may also be desirable to use finishing steps and/or post treatment processes to impart selected properties to the composite fabric 36. For example, the fabric 36 may be lightly pressed by calender rolls, creped, brushed or otherwise treated to enhance stretch and/or to provide a uniform exterior appearance and/or certain tactile properties. Alternatively  
25 or additionally, various chemical post-treatments such as, adhesives or dyes may be added to the fabric 36. Additional post-treatments that can be utilized are described in U.S. Patent No. 5,853,859 to Levy, et al., which is incorporated herein in its entirety by reference thereto for all  
30 purposes.

The basis weight of the fabric of the present invention can generally range from about 20 to about 200 grams per square meter (gsm), and particularly from about 35 gsm to about 100 gsm. Lower basis weight products are typically well suited for use as light duty wipers, while the higher basis weight products are better adapted for use as industrial wipers. The present invention may be better understood with reference to the following example.

#### EXAMPLE 1

The ability to form an entangled fabric in accordance with the present invention was demonstrated. Initially, a 0.5 osy point bonded spunbond web was formed. The spunbond web contained pentalobal splittable fibers formed from a Nylon sheath (Nylene 401 from Custom Resins) and polyethylene core (Dow 6811). The splittable fibers had a denier per filament of 3.0. The degree of creping of the spunbond web was 15%. The spunbond web was then hydraulically entangled on a coarse wire with a pulp fiber component at an entangling pressure of 1500 pounds per square inch. The resulting fabric had a basis weight of 122 grams per square meter, and contained 20% by weight of the spunbond web and 80% of the pulp fiber component.

Once formed, the "viscous oil absorption" and "web permeability" of the fabric were determined as follows.

#### Viscous Oil Absorption Efficiency Method

Viscous Oil Absorption is a method used to determine the ability of a fabric to wipe viscous oils. A sample of the web is first mounted on a padded surface of a sled (10 cm x 6.3 cm). The sled is mounted on an arm designed to traverse the sled across a rotating disk. The sled is then weighted so that the combined weight of the sled and sample is about 768 grams. Thereafter, the sled and traverse arm are positioned on a horizontal rotatable disc with the sample being pressed against the surface of the disc by the weighted sled. Specifically, the sled and traverse arm

are positioned with the leading edge of the sled (6.3 cm side) just off the center of the disc and with the 10 cm centerline of the sled being positioned along a radial line of the disc so that the trailing 6.3 cm edge is positioned near the perimeter of the disc.

5 One (1) gram of an oil is then placed on the center of the disc in front of the leading edge of the sled. The disc, which has a diameter of about 60 centimeters, is rotated at about 65 rpm while the traverse arm moves the sled across the disc at a speed of about 2 1/2 centimeters per second until the trailing edge of the sled crosses off the outer edge of the disc. At this point, the test is stopped. The wiping efficiency is evaluated by measuring the change in weight of the wiper before and after the wiping test. The fractional wiping efficiency is determined by dividing the increase in weight of the wiper by one (1) gram (the total oil weight). The test described above is performed under constant temperature and relative humidity conditions (70° F  $\pm$  2° F and 65% relative humidity).

#### Web Permeability Measurement Method

Web permeability is obtained from a measurement of the resistance by the material to the flow of liquid. A liquid of known viscosity is forced through the material of a given thickness at a constant flow rate and the resistance to flow, measured as a pressure drop is monitored. Darcy's Law is used to determine permeability as follows:

$$\text{Permeability} = [\text{flow rate} \times \text{thickness} \times \text{viscosity} / \text{pressure drop}]$$

where the units are as follows:

permeability:	cm <sup>2</sup> or darcy (1 darcy = 9.87 x 10 <sup>-9</sup> cm <sup>2</sup> )
flow rate:	cm/sec
viscosity:	pascal-sec
pressure drop:	pascals

The apparatus includes an arrangement wherein a piston within a cylinder pushes liquid through the sample to be measured. The sample is clamped between two aluminum cylinders with the cylinders oriented

vertically. Both cylinders have an outside diameter of 3.5", an inside diameter of 2.5" and a length of about 6". The 3" diameter web sample is held in place by its outer edges and hence is completely contained within the apparatus. The bottom cylinder has a piston that is capable of moving vertically within the cylinder at a constant velocity and is connected to a pressure transducer that capable of monitoring the pressure of encountered by a column of liquid supported by the piston. The transducer is positioned to travel with the piston such that there is no additional pressure measured until the liquid column contacts the sample and is pushed through it. At this point, the additional pressure measured is due to the resistance of the material to liquid flow through it. The piston is moved by a slide assembly that is driven by a stepper motor.

The test starts by moving the piston at a constant velocity until the liquid is pushed through the sample. The piston is then halted and the baseline pressure is noted. This corrects for sample buoyancy effects. The movement is then resumed for a time adequate to measure the new pressure. The difference between the two pressures is the pressure due to the resistance of the material to liquid flow and is the pressure drop used in the Equation set forth above. The velocity of the piston is the flow rate. Any liquid whose viscosity is known can be used, although a liquid that wets the material is preferred since this ensures that saturated flow is achieved. The measurements were carried out using a piston velocity of 20 cm/min, mineral oil (Penetec Technical Mineral Oil manufactured by Penreco of Los Angeles, CA) of a viscosity of 6 centipoise. This method is also described in US Patent 6,197,404 to Varona, et al.

After performing the tests set forth above, it was determined that the viscous oil absorption was 78% and the web permeability was 112 darcies. Such a high oil absorption and web permeability generally reflect the ability of the fabric of the present invention to be utilized as a wiper to absorb oils and other materials.

**EXAMPLE 2**

5 The ability to form an entangled fabric in accordance with the present invention was demonstrated. Initially, a 0.5 osy point bonded spunbond web was formed. The spunbond web contained pentalobal splittable fibers formed from a Nylon sheath (Nylene 401 from Custom Resins) and polyethylene core (Dow 6811). The splittable fibers had a denier per filament of 3.0. The degree of creping of the spunbond web was 15%. The spunbond web was then hydraulically entangled on a coarse wire with a pulp fiber component at an entangling pressure of 1500 pounds per square inch. The resulting fabric had a basis weight of 85 grams per square meter, and contained 30% by weight of the spunbond web and 70% of the pulp fiber component.

10 The "viscous oil absorption" of the resulting fabric was 82% and the "web permeability" was 128 darcies. After performing the tests set forth above, it was determined that the viscous oil absorption was 78% and the web permeability was 112 darcies. Such a high oil absorption and web permeability generally reflect the ability of the fabric of the present invention to be utilized as a wiper to absorb oils and other materials.

15 While the invention has been described in detail with respect to the specific embodiments thereof, it will be appreciated that those skilled in the art, upon attaining an understanding of the foregoing, may readily conceive of alterations to, variations of, and equivalents to these embodiments. Accordingly, the scope of the present invention should be assessed as that of the appended claims and any equivalents thereto.

20
